

CPSV-Editor & Linked Data Explorer

Both Apps run on the rapid-prototyping track – acc and main, gated by GitHub Actions. The standard delivery pipeline does not exist yet.

TODAY – ALL DELIVERY HAPPENS HERE, ON ACC AND MAIN, GATED BY GITHUB ACTIONS

Three controls, gated in CI – with no standard software delivery aligned yet

01 – BUILD PROVENANCE

“Which build am I looking at?”

Every environment states the exact source and build it is serving. A hand-written version number never could.

02 – SUPPLY-CHAIN VERIFICATION

“Is the pin telling the truth?”

Standard tooling only checks that a dependency is pinned to a fingerprint. We now re-resolve that fingerprint against source – a wrong or hostile one used to pass every review.

03 – TEST-COVERAGE FLOOR

“Is this code actually tested?”

80% of decision paths tested in every file – so a well-tested utility can no longer pay for an untested screen.

IN PLACE – CI GATING

GitHub Actions workflows block any merge – **acc** or **main** – when a control fails.

MISSING – DELIVERY PIPELINE

Both branches stay inside prototyping: no pipeline, no production-ready deployment beyond them.

GATED IN CI TODAY

All three controls in place and blocking

Tests run before a merge

Formatting checked in CI

CPSV Editor

Yes

Yes

Yes

Linked Data Explorer

Yes

Yes

Yes

Five items, all closed

Every item raised in the CI posture review is closed in both repositories, and acc and main are in sync. Nothing on the prototyping track is holding this decision up.

WHAT THIS MEANS

The prototyping track is finished work, not work in progress.

The remaining gap is the graded release path above it — the thing you are asked to approve.

✓ Last coverage exemption cleared

CPSV · #103

The last legacy file below the 80% floor is now covered, so the bespoke script is retired in favour of standard tooling.

✓ Pin register kept in step with the bumps

Both

Automated dependency bumps now update the pins and the register that records them on the same branch — a mechanism, not a habit.

✓ Zero margin on the coverage floor

Explorer

The files sitting at or just above the 80% line have been given headroom, so an unrelated change no longer turns CI red.

✓ Formatting checked on the shared branch

CPSV

Now checked in CI on the shared branch in both repositories, not only by a hook on a developer's machine.

✓ Production build ids confirmed once

Both

Confirmed on both main and acc: each branch's build reports the exact commit it was made from.

ASK

Start the initial clean

Rinse the CPSV-Editor and the Linked Data Explorer, and stand up the standard delivery pipeline behind them — a Wasstraat quality gate, then build, test and deploy to a production-ready release. Today's acc-and-main track stays in service for rapid prototyping.

WHAT IT BUYS

A delivery path separate from experimentation — a release stops moving every time someone tries something.

The three controls become gates on a deployment, not only on a merge between prototyping branches.

A quality gate — the Wasstraat — that nothing reaches users without passing.

WHAT IT COSTS

Building the delivery pipeline and the Wasstraat gate: a one-off engineering investment.

One clean-up pass on each application before it can be the first pipeline release.

Prototype work then reaches a deployment on a six-month merge, not the day it is written.

WHAT IT DELIVERS

Production-ready, graded applications — deployed through a pipeline rather than promoted between prototyping branches.

The three CI controls stop being the last word and become the entry condition for a release.

Rapid prototyping keeps its speed on acc and main — it stays the track where things are tried, not the track that ships.

Status verified against the **main** branch of both repositories — ttl-editor and linked-data-explorer — with acc and main in sync on the latest versions.

What changed in this version

Six corrections, so nothing in the earlier framing is carried forward silently.

TOPIC	FIRST VERSION	UPDATED VERSION
Branch model	acc and main split across the two tracks	acc and main are both rapid prototyping: accept on acc, promote to main
Prototyping track	Framed as running “with no pipeline behind it”	Framed accurately: real CI/CD, every merge gated by GitHub Actions
What is missing	A CI/CD pipeline of any kind	The standard delivery pipeline beyond prototyping, ending in a production-ready deployment
Open items	Five items, three closed	Five items, all closed — a delivery report rather than a backlog
Slide 4, third column	“If we do nothing”	“What it delivers” — graded applications without losing prototyping speed
Status verification	Acceptance-branch commit per repository	main branch of both repositories, with acc and main in sync
